Advanced Analysis

1. Purpose: I needed to identify several key functions and variables in order to begin formulating a trainer. I specifically looked for timer variables, win functions, and sought to find the board representation.

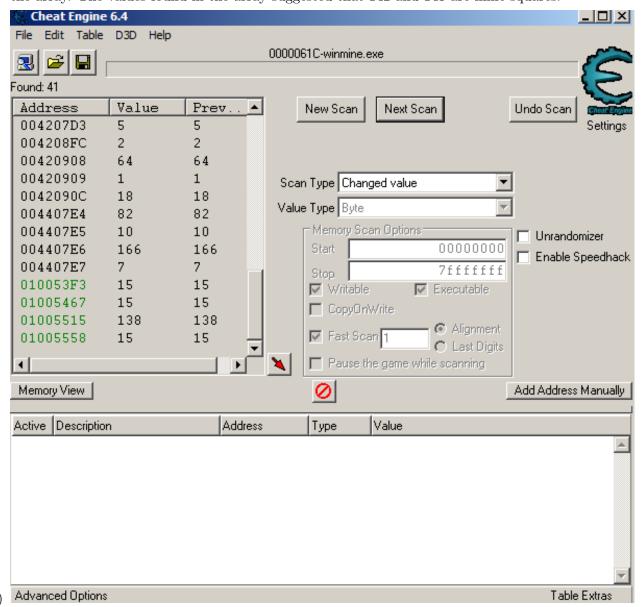

2. AUTO WIN:

(a) I started by poking through IDA functions and through some luck, stumbled onto the function called during a click. This was made evident by the two integer arguments it took and the structure of the function.

```
ClickBox proc near
                                           xCoord= dword ptr
                                          yCoord= dword ptr
                                                   eax, [esp+yCoord]
                                           mov
                                           push
                                                   ebx
                                          push
                                                   ebp
                                          push
                                                   esi
                                           mov
                                                   esi, [esp+0Ch+xCoord]
                                           mov
                                                   ecx, eax
                                           sh1
                                                   ecx, 5
                                                   edx, mineData[ecx+esi]
                                           1ea
                                           test
                                                   byte ptr [edx], 80h
                                           push
                                                   short loc_1003595
                                           jz
                  dword_10057A4, 0
         cmp
                 short loc_1003588
         jnz
(b)
```

- (c) Having this, all I needed was to be able to detect if a certain square was a mine. I downloaded cheatengine and used it to scan the memory loaded by Minesweeper.
- (d) I didn't know exactly where the mines were stored so I scanned once getting all bytes.

(e) I changed the board and made another scan for changed values. Repeating this a couple times and poking through IDA to confirm my findings, I was able to get the address of the array. The values found in the array suggested that 142 and 143 are mine squares.

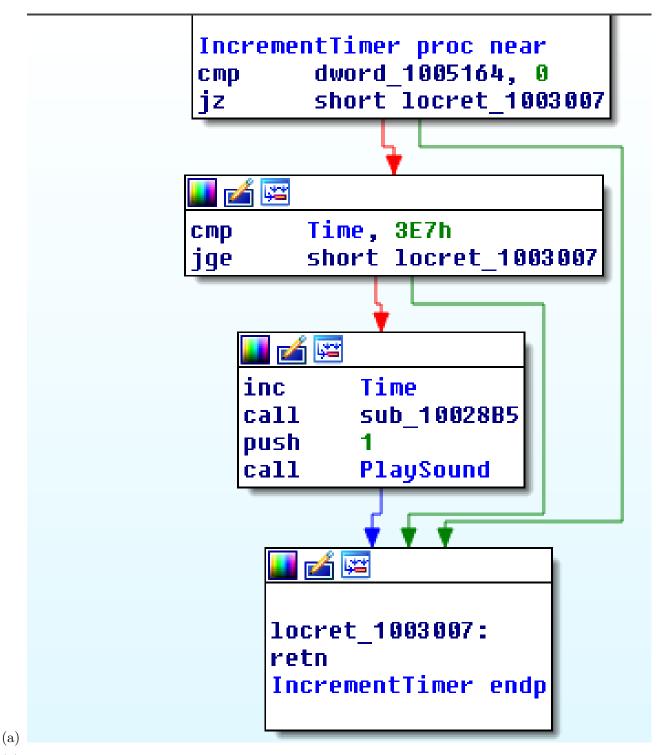

(g) From there it was a simple matter to loop through the board and call click on all squares which were not mines!

3. Show Mines:

(a) Looking through the click function I had my next breakthrough. I found a function calling getDC, and after some google-fu it become clear that this function was used to draw graphics on various squares. Nifty!

```
stdcall reDrawSquare(int xCoord, int yCoord, char a3)
   reDrawSquare proc near
   xCoord= dword ptr
   yCoord= dword ptr
   arg 8= byte ptr
                     0Ch
   mov
           eax, [esp+yCoord]
   mov
           ecx, [esp+xCoord]
           [esp+yCoord]
   push
   sh1
           eax, 5
           eax, mineData[eax+ecx]
   lea.
   mov
           dl, [eax]
   and
           d1, 0E0h
   or
           dl, [esp+4+arg_8]
   push
           ecx
   mov
           [eax], dl
   call
           UpdateSquareImage
   retn
           0Ch
   reDrawSquare endp
(b)
```

- (c) Now that I had a method to draw on squares I just needed to figure out what argument provided an acceptable drawing. I chose the ? and found it through more cheatengine analysis and guessing.
- 4. Freeze Timer:

- (b) A little more poking around and I found this highly suggestive function which I correctly assumed was the timer increment function. Seems hookable.
- (c) I downloaded, built and linked the detours library. After looking at the previous lab and other examples I got a hook set on the previously found timer function.

(d) This hook simply nops freezing the timer.

5. Inert Mines:

- (a) I took a very similar approach to the previous problem, I simply hooked the click function and if the square was a mine drew a? instead of calling the click function.
- (b) If the square was not a mine the trampoline was called and the real click function is executed.

6. Extract Layout:

- (a) Surprisingly this gave me the most trouble of all the tasks. For some reason I simply could not get the array to play nicely and my attempts to calculate the hidden squares were resulting in silent failures.
- (b) After a few hours of horrifying debug statements using messagebox I decided that the prompt never said anything about side effects and having already built the autowin function, simply solved the board and read the resulting tiles from memory.
- (c) This was much easier.
